

AMENDMENTS TO THE CLAIMS

Please amend Claims 1, 10, 17, 27, 28, and 30 as indicated below.

1. (Currently Amended) An audio enhancement system uniquely adapted for use in a near-field audio reproduction system, the audio enhancement system comprising:

a first high-pass filter which receives first audio information on a first input, the first high-pass filter configured to filter a set of lower frequencies—bass components in the first input relative to other frequencies in the first input to create first filtered audio information wherein at least a portion of the bass components are removed from the first audio information;

a second high-pass filter which receives second audio information on a second input, the second high-pass filter configured to filter a set of lower frequencies—bass components in the second input relative to other frequencies in the second input to create second filtered audio information wherein at least a portion of the base components are removed from the second audio information;

a difference circuit that receives the filtered—first filtered audio information and the second filtered audio information inputs—supplied by—an audio reproduction—system, wherein the difference circuit identifies difference information in the first and second filtered audio information inputs;

an equalizer in communication with the difference circuit, the equalizer configured to modifying the frequency response of the difference information to create processed difference information having a level of equalization varying with respect to the frequency component of the processed difference information, wherein the level of equalization is adapted to exploit the acoustics of a human ear and especially those unique to a near-field audio system, the level of equalization comprising:

a maximum gain occurring at a maximum-gain frequency of approximately 100 to 150 Hz, a minimum gain occurring at a minimum-gain frequency of approximately 1680 to 2520 Hz, and a mid-gain of

approximately one-half the difference between the maximum gain and the minimum gain occurring at a mid-gain frequency of approximately 5600 to 8400 Hz;

bass attenuation of the difference information relative to the maximum gain, the bass attenuation occurring below the maximum-gain frequency and increasing with a reduction in difference-information frequency to prevent over amplification of a speaker; and

attenuation of the difference information relative to the maximum gain at a mid-range of frequencies, the attenuation occurring above the maximum gain frequency and increasing with a corresponding increase in difference-information frequency up to the minimum-gain frequency, the attenuation decreasing above the minimum-gain frequency with an increase in difference-information frequency up to the mid-gain frequency; and

a summing circuit that combines the processed difference information with at least a portion of the bass components in the first audio information that were removed by the first high-pass filter set of lower frequencies in the first input to create an enhanced first output that comprises at least a portion of the bass components and at least a portion of the processed difference information, and

the summing circuit also configured to combine the processed difference information with at least a portion of the bass components in the second audio information that were removed by the second high-pass filter set of lower frequencies in the second input to create an enhanced second output that comprises at least a portion of the bass components and at least a portion of the processed difference information.

2. (Previously Presented) The audio enhancement system of Claim 1 wherein the difference circuit, the equalizer and the summing circuit are implemented in a digital signal processor.

3. (Previously Presented) The audio enhancement system of Claim 1 wherein the bass attenuation increases at a rate of approximately 6 decibels per octave, the mid-range attenuation increases below the minimum-gain frequency at a rate of approximately 6 decibels per octave, and the mid-range attenuation decreases above the minimum-gain frequency at a rate of approximately 6 decibels per octave.

4. (Original) The audio enhancement system of Claim 1 further comprising an attenuator that attenuates the difference information by a fixed amount substantially across an audible frequency spectrum.

5. (Previously Presented) The audio enhancement system of Claim 1, wherein the first and second high-pass filters attenuate very low frequency components of the first and second inputs.

6. (Previously Presented) The audio enhancement system of Claim 5 wherein the first and second high-pass filters are implemented in a digital signal processor.

7. (Previously Presented) The audio enhancement system of Claim 6 wherein the first and second high-pass filters have a cutoff frequency in the range of 125 to 200 Hz.

8. (Original) The apparatus of Claim 1 further comprising a level adjust circuit in communication with the difference circuit, the level adjust circuit configured to adjust the level of the difference information.

9. (Canceled)

10. (Currently Amended) An apparatus for enhancing sound, the apparatus comprising:

a first high-pass filter which receives first audio information on a first input, the first high-pass filter configured to filter bass components from the first audio information to create first filtered information wherein at least a portion of bass components have been filtered from the first audio information—a set of lower frequencies in the first input relative to other frequencies in the first input;

a second high-pass filter which receives second audio information on a second input, the second high-pass filter configured to filter bass components from the second audio information to create second filtered audio information wherein at least a portion of the bass components have been filtered from the second audio information~~set of lower frequencies in the second input relative to other frequencies in the second input~~;

a difference circuit in communication with the first and second high-pass filters, the difference circuit configured to identify the difference information in the filtered first and second filtered audio information~~inputs~~;

an equalizer in communication with the difference circuit, the equalizer configured to spectrally shape the difference information; and

a summing circuit in communication with the equalizer and the first input and the second input, the summing circuit configured to combine the spectrally shaped difference information with a portion of the bass components that were filtered from set of lower frequencies in the first audio information on the first input to generate a first output comprising at least a portion of the bass components in the first audio information and at least a portion of the spectrally shaped difference information, the summing circuit further configured to combine the spectrally shaped difference information with the bass components that were filtered from set of lower frequencies in the second audio information on the second input to generate a second output comprising at least a portion of the bass components in the second audio information and at least a portion of the spectrally shaped difference information; and -

wherein the difference information is spectrally shaped by the equalizer by applying a perspective curve characterized by a maximum gain within a first frequency range of 100 to 150 Hz and the curve characterized by a minimum gain within a second frequency range of 1680 to 2520 Hz, wherein the curve decreases at a rate of approximately 6 decibels per octave below the first frequency range and above the first frequency range towards the second

frequency range, the curve further increasing at a rate of approximately 6 decibels per octave above the second frequency range.

11. (Original) The apparatus of Claim 10 wherein the maximum gain and the minimum gain are separated by approximately 12 decibels.

12. (Previously Presented) The apparatus of Claim 10 wherein the perspective curve is adjustable to raise or lower the maximum and minimum-gain frequencies with the maximum-gain range and the minimum-gain range.

13. (Previously Presented) The apparatus of Claim 10 further comprising a level adjust circuit in communication with the difference circuit, the level adjust circuit configured to adjust the level of the difference information.

14. (Previously Presented) The apparatus of Claim 10 wherein the first and second high-pass filters, the difference circuit, the equalizer, and the summing circuit are implemented in a digital signal processor.

15. (Previously Presented) The apparatus of Claim 10 further comprising an attenuator that attenuates the difference information by a fixed amount substantially across an audible frequency spectrum.

16. (Canceled)

17. (Currently Amended) An apparatus for enhancing sound, the apparatus comprising:

a first input and a second input wherein the first and second inputs comprise first and second audio information with bass components and at least a set of lower frequencies relative to other frequencies;

a difference circuit configured to identify difference information in the first and second inputs, wherein at least a portion of the bass components in the first and second inputs are removed from the difference information;

an equalizer configured to spectrally shape the difference information in the first and second inputs, wherein the difference information is spectrally shaped by the equalizer by applying a perspective curve characterized by a

maximum gain within a first frequency range of 100 to 150 Hz and the curve characterized by a minimum gain within a second frequency range of 1680 to 2520 Hz, wherein the curve decreases at a rate of approximately 6 decibels per octave below the first frequency range and above the first frequency range towards the second frequency range, the curve further increasing at a rate of approximately 6 decibels per octave above the second frequency range, and wherein the equalizer does not spectrally shape the sets of lower frequencies; and

a summing circuit configured to combine the spectrally shaped difference information with at least a portion of the bass components removed from the difference information, set of lower frequencies in the first input to generate a first output comprising at least a portion of the bass components and the spectrally shaped difference information, and

the summing circuit further configured to combine the spectrally shaped difference information with at least a portion of the set of lower frequencies in the second input bass components removed from the difference information to generate a second output comprising at least a portion of the bass components and the spectrally shaped difference information.

18. (Original) The apparatus of Claim 17 wherein the maximum gain and the minimum gain are separated by approximately 12 decibels.

19. (Previously Presented) The apparatus of Claim 17 wherein the perspective curve is adjustable to raise or lower the maximum and minimum-gain frequencies with the maximum-gain range and the minimum-gain range.

20. (Previously Presented) The apparatus of Claim 17 further comprising a level adjust circuit in communication with the difference circuit, the level adjust circuit configured to adjust the level of the difference information.

21. (Previously Presented) The apparatus of Claim 17 wherein the difference circuit, the equalizer, and the summing circuit are implemented in a digital signal processor.

22. (Previously Presented) The apparatus of Claim 17 further comprising an attenuator that attenuates the difference information by a fixed amount substantially across an audible frequency spectrum.

23. (Canceled)

24. (Canceled)

25. (Canceled)

26. (Canceled)

27. (Currently Amended) A method for enhancing sound, the method comprising:

receiving at least a first input and a second input, wherein the first and second inputs comprise at least a first set of bass components ~~lower frequencies~~ and a second set of other ~~frequencies that occur at a range of frequencies that are higher than the first set of lower frequencies;~~

spectrally shaping difference information in the first and second inputs wherein at least a portion of the bass components have been filtered, wherein spectrally shaping the difference information boosts the amplitudes of the second set of frequencies ~~relative to the amplitudes of the first set of lower frequencies;~~

combining the spectrally shaped difference information with at least a portion of the bass components ~~first set of lower frequencies~~ in the first ~~input and second inputs~~ to generate ~~an a first output that contains comprises at least a portion of the bass components in the first input and the spectrally shaped difference information and the portion of the first set of lower frequencies;~~

wherein spectrally shaping the difference information further reduces the amplitudes of a third set of frequencies relative to the amplitudes of the second set of frequencies, the third set of frequencies occurring at higher frequencies than the second set of frequencies; and

wherein a maximum reduction of the amplitudes of the third set of frequencies occurs at approximately 2.1 kilohertz.

28. (Currently Amended) A method for enhancing sound, the method comprising:

receiving at least a first input and a second input, wherein the first and second inputs comprise at least a first set of bass components ~~lower frequencies~~ and a second set of other ~~frequencies that occur at a range of frequencies that are higher than the first set of lower frequencies;~~

spectrally shaping difference information in the first and second inputs, wherein spectrally shaping the difference information boosts the amplitudes of the second set of frequencies ~~relative to the amplitudes of the first set of lower frequencies;~~

combining the spectrally shaped difference information with at least a portion of the first set of bass components ~~first set of lower frequencies~~ in the first input ~~and second inputs~~ to generate an output that contains the spectrally shaped difference information and the portion of the bass components in the first input ~~first set of lower frequencies;~~

wherein spectrally shaping the difference information further reduces the amplitudes of a third set of frequencies relative to the amplitudes of the second set of frequencies, the third set of frequencies occurring at higher frequencies than the second set of frequencies; and wherein spectrally shaping the difference information further boosts the amplitudes of a fourth set of frequencies relative to the amplitudes of the third set of frequencies, the fourth set of frequencies occurring at higher frequencies than the third set of frequencies.

29. (Previously Presented) The method of Claim 28 wherein a maximum boost of the amplitudes of the fourth set of frequencies occurs above approximately 2.1 kilohertz.

30. (Currently Amended) A method for enhancing sound, the method comprising:

receiving at least a first input and a second input, wherein the first and second inputs comprise a first set of bass components and at least a first set of lower frequencies and a second set of frequencies that occur at a range of other frequencies that are higher than the first set of lower frequencies;

spectrally shaping difference information in the first and second inputs, wherein spectrally shaping the difference information modifies the amplitudes of the second set of frequencies ~~such that the amplitudes of the second set of frequencies are greater than the amplitudes of the first set of lower frequencies;~~ and

combining the spectrally shaped difference information with at least a portion of the bass components first set of lower frequencies in the first input and second inputs to generate an output that contains comprises the portion of the bass components in the first input and the spectrally shaped difference information ~~and the portion of the first set of lower frequencies;~~

wherein spectrally shaping the difference information further modifies the amplitudes of a third set of frequencies such that the amplitudes of the third set of frequencies are less than the amplitudes of the second set of frequencies, the third set of frequencies occurring at higher frequencies than the second set of frequencies; and

wherein spectrally shaping the difference information further modifies the amplitudes of a fourth set of frequencies such that the amplitudes of the third set of frequencies are greater than the amplitudes of the third set of frequencies, the fourth set of frequencies occurring at higher frequencies than the third set of frequencies.

31. (Previously Presented) The audio enhancement system of Claim 30 wherein spectrally shaping the difference information is performed by a digital signal processor.
